1. Note down 3 things you know about light.

A Light travels in straight lines

B Light is a form of energy

C Light can be reflected / refracted / diffracted

The exhibit contains the world’s most expensive rubies. Can you arrange the mirrors so the laser beam acts as a burglar alarm—illuminating as many rubies as possible?

2. Choose one of the mirror pillars that is reflecting light. You are going to measure the angle at which the light travels into and away from the mirror. Measure from the middle line (the normal) of the protractor. Repeat the measurements for 4 different angles at which the light hits the mirror.

<table>
<thead>
<tr>
<th>Angle of incidence</th>
<th>Angle of reflection</th>

</tbody>
</table>

3. What pattern do you notice?

4. Using what you have observed, complete the diagram below.

\[ \text{angle of incidence} (\text{light coming in}) \quad \text{angle of reflection} (\text{light leaving}) \]

The angle of refraction should be the same as the angle of incidence, with an directional arrow and labelled ‘r’.

Remember your straight lines!
**REFLECT IT**

5. On the diagram below, show the path of the laser beam as it reflects off the mirrors. Which ruby will the laser illuminate? Use a ruler and include arrows to show the direction of the beam.

6. Some other ways in which we use lasers include:
   - Optical disk drives
   - Laser printers
   - Barcode scanners
   - Fibre-optic cables
   - Laser surgery and skin treatments
   - Cutting and welding
   - Measuring range and speed (e.g., moving vehicles)
   - Laser lighting displays in entertainment.

**REFLECT IT**

Most light sources emit light in many different directions at once. In lasers, the light waves are all parallel to one another.

7. How might this property of lasers be useful?
   (Hint: think about your suggestions for the ways in which we use them).
   - The beam can be very directional / can be focused on a small point.
   - The (light) energy can be focused / concentrated.
   - We can see the laser beam because the light energy is reflected off dust particles and surfaces, and this light enters our eyes.

8. What two differences in the laser beam do you notice between the start and at its furthest point?
   - The beam is less bright at the furthest point.
   - The beam is less focussed / spreads out / disperses the further it travels.

9. How can you explain this?
   - The brightness is related to the amount of (light) energy in the beam.
   - Some of this energy gets absorbed and/or scattered by the dust particles. The further the beam travels, the more light energy is lost.

10. How could you make the beam invisible?
    - Have the beam travel thoroughly a gas that is completely free of dust / suspended particles.
    - And / or have the beam travel through a vacuum.
